**Background:** YB-1 is a multifunctional protein that affects transcription, splicing, and translation.

**Results:**  $\Delta$ Np63 $\alpha$ , the main p63 protein isoform, interacts with YB-1 and affects YB-1 subcellular localization and regulation of cell survival and motility genes.

**Conclusion:**  $\Delta$ Np63 $\alpha$  and YB-1 interaction inhibits epithelial to mesenchymal transition and tumor cell motility.

**Significance:** This is the first demonstration of a physical and functional interaction between YB-1 and  $\Delta$ Np63 $\alpha$  oncoproteins.

The Y-box binding protein 1 (YB-1) belongs to the cold-shock domain protein superfamily, one of the most evolutionarily conserved nucleic acid-binding proteins currently known. YB-1 performs a wide variety of cellular functions, including transcriptional and translational regulation, DNA repair, drug resistance, and stress responses to extracellular signals. Inasmuch as the level of YB-1 drastically increases in tumor cells, this protein is considered to be one of the most indicative markers of malignant tumors. Here, we present evidence that  $\Delta$ Np63 $\alpha$ , the predominant p63 protein isoform in squamous epithelia and YB-1, can physically interact. Into the nucleus,  $\Delta$ Np63 $\alpha$  and YB-1 cooperate in *PI3KCA* gene promoter activation. Moreover,  $\Delta$ Np63 $\alpha$  promotes YB-1 nuclear accumulation thereby reducing the amount of YB-1 bound to its target transcripts such as that encoding the SNAIL1 protein. Accordingly,  $\Delta$ Np63 $\alpha$  enforced expression was associated with a reduction of the level of SNAIL1, a potent inducer of epithelial to mesenchymal transition. Furthermore,  $\Delta$ Np63 $\alpha$  depletion causes morphological change and enhanced formation of actin stress fibers in squamous cancer cells. Mechanistic studies indicate that  $\Delta$ Np63 $\alpha$  affects cell movement and can reverse the increase of cell motility induced by YB-1 overexpression. These data thus suggest that  $\Delta$ Np63 $\alpha$  provides inhibitory signals for cell motility. Deficiency of  $\Delta$ Np63 $\alpha$  gene expression promotes cell mobilization, at least partially, through a YB-1-dependent mechanism.

The Y-box binding protein 1 (YB-1), also known as NSEP1, CSBD, and MDR-NF1, is a member of the highly conserved Y-box family of proteins that regulate gene transcription by binding to the TAACC element (the Y-box) contained within many eukaryotic promoters (1). Transcriptional targets of YB-1 include genes associated with cell death, cell proliferation, and

multidrug resistance (1, 2). YB-1 protein can also regulate gene transcription by binding to other transcription factors such as p53, AP1, and SMAD3 (2).

YB-1 is an important marker of tumorigenesis and is overexpressed in many malignant tissues, including breast cancer, non-small cell lung carcinoma, ovarian adenocarcinoma, human osteosarcomas, colorectal carcinomas, and malignant melanomas (1). Mostly cytosolic, YB-1 protein shuttles between the nucleus and cytoplasm. Cytoplasmic YB-1 acts as a translation factor of oncogenic/pro-metastatic genes (3). It binds to the mRNA cap structure and displaces the eukaryotic translation initiation factors eIF4E and eIF4G, thereby causing mRNA translational silencing (4). However, cytoplasmic YB-1 activates cap-independent translation of mRNA encoding SNAIL1, a transcription factor that promotes epithelial-mesenchymal transition by suppressing E-cadherin (5). According to those observations, the YB-1 protein level, in breast carcinoma, is positively correlated to the increase of SNAIL1 protein level and reduced expression of E-cadherin (6).

In normal conditions, YB-1 is located in the cytoplasm and transiently translocates to the nucleus at the G<sub>1</sub>/S transition of the cell cycle (7). Moreover, nuclear translocation of YB-1 was shown to occur in response to DNA-damaging agents, phosphorylation at Ser-102 by AKT kinase, UV irradiation, TGF $\beta$  stimulation, virus infection, hypothermia, and pharmacological compounds (1, 8, 9). Under stress stimuli, YB-1 nuclear translocation requires a physical interaction with wild type p53 (10).

Herein, we report that YB-1 directly interacts with  $\Delta$ Np63 $\alpha$  and accumulates in the nuclear compartment.  $\Delta$ Np63 $\alpha$  is encoded by the *TP63* locus, a homologue of the p53 tumor suppressor gene and the most ancient member of the p53 family (11). Because of the presence of two promoters, the *TP63* gene encodes two major classes of proteins as follows: those containing a transactivating domain homologous to the one present in p53 (*i.e.* TAp63), and those lacking it (*i.e.*  $\Delta$ Np63) (12). In addition, alternate splicing at the C terminus generates at least three p63 variants ( $\alpha$ ,  $\beta$ , and  $\gamma$ ) in each class. The TAp63 $\gamma$  isoform

resembles most p53, whereas the  $\alpha$ -isoforms include a conserved protein-protein interaction domain named the sterile  $\alpha$  motif.

Gene knock-out mice demonstrated that p63 plays a critical role in the morphogenesis of organs/tissues developed by epithelial-mesenchymal interactions such as the epidermis, teeth, hair, and glands (13). In adults,  $\Delta$ Np63 $\alpha$  expression occurs in the basal cells of stratified epithelia. High expression of  $\Delta$ Np63 $\alpha$  is associated with the proliferative potential of epithelial cells (14) and is enhanced at the early stages of squamous cell carcinomas (SCCs)<sup>2</sup> (15). Down-regulation of  $\Delta$ Np63 $\alpha$  by SNAIL transcription factor instead was found to reduce cell-cell adhesion and increase the migratory properties of squamous carcinoma cells (16). Moreover, a partial or complete loss of  $\Delta$ Np63 $\alpha$  expression was associated with tumor metastasis supporting the idea that  $\Delta$ Np63 $\alpha$  plays a relevant role in metastasis suppression (17, 18). Here, we provide experimental evidence that the YB-1 protein associates with  $\Delta$ Np63 $\alpha$  and such interaction plays a critical role in the control of genes involved in cell survival and motility.

### EXPERIMENTAL PROCEDURES

**Plasmids**—cDNAs encoding human FLAG-tagged YB-1 were provided by Dr. Sandra Dunn (Research Institute for Children's and Women's Health, Vancouver, British Columbia, Canada). *PIK3CA* promoter luciferase plasmid was provided by Dr. Arezoo Astanehe (Research Institute for Children's and Women's Health, Vancouver, British Columbia, Canada). cDNA encoding human  $\Delta$ Np63 $\alpha$  and  $\Delta$ Np63 $\gamma$  were previously described (19). For bacterial expression,  $\Delta$ Np63 $\gamma$  and  $\Delta$ Np63 $\alpha$  cDNAs were inserted in pRSETA vector in XhoI/ClaI and XhoI/XbaI (filled) sites, respectively. GFP and YB-1-GFP vectors were provided by Dr. Paul R. Mertens (University Hospital Aachen, Germany). PET-YB-1 was from Dr. Jill Gershan (Medical College of Wisconsin, Milwaukee, WI).

**Cell Lines, Transfection, and Antibodies**—Squamous carcinoma cells (SCC011 and SCC022) were described previously and provided to us by Dr. C. Missero (20).

These cell lines were maintained in RPMI medium supplemented with 10% fetal bovine serum at 37 °C and 5% CO<sub>2</sub>. A431, H1299, and MDA-MB-231 cells were obtained from ATCC and maintained in DMEM supplemented with 10% fetal bovine serum at 37 °C and 5% CO<sub>2</sub>. Dox-inducible Tet-On H1299/ $\Delta$ Np63 $\alpha$  cells were described previously (21).

Lipofections were performed with Lipofectamine (Invitrogen), according to the manufacturer's recommendations. *YB-1* transient silencing was carried out with ON-TARGET plus SMART pool *YB-1*-siRNA (Dharmacon) and RNAiMAX reagent (Invitrogen).  $\Delta$ Np63 $\alpha$  transient silencing in SCC011 cells was carried out with RIBOXX (IBONI p63-siRNA pool) and RNAiMAX reagent (Invitrogen), according to the manufacturer's recommendation. An si-RNA against luciferase (si-Luc) was used as a negative control. Anti-p63 (4A4) and anti-

actin(1–19) were from Santa Cruz Biotechnology Inc., and anti-FLAG M2 was from Sigma. PARP, AKT, pAKT (Ser-473) and rabbit polyclonal YB-1 antibody (Ab12148) were from Cell Signaling Technology (Beverly, MA). Mouse monoclonal E-cadherin (ab1416) and SNAIL1 antibodies were from Abcam (Cambridge, UK). Mouse monoclonal N-cadherin (610921) was from BD Transduction Laboratories. Cy3-conjugated anti-mouse IgG and Cy5-conjugated anti-rabbit IgG were from Jackson ImmunoResearch. Doxycycline was from Clontech.

**Chromatin Immunoprecipitation (ChIP) Assay**—ChIP was performed with chromatin from human MDA-MB-231 cells transfected with  $\Delta$ Np63 $\gamma$ ,  $\Delta$ Np63 $\alpha$ , and/or FLAG YB-1, as described previously (22). Real time PCR was performed with the 7500 Applied Biosystems apparatus and SYBR Green MasterMix (Applied Biosystems) using the following oligonucleotides: *PIK3CA*-For, CCCCCGAACCTAATCTCGTTT, and *PIK3CA*-Rev, TGAGGGTGTGTGTGCATCCT.

Sequential ChIP was performed with chromatin from SCC011 cells. Method of chromatin extraction and controls used were previously described (22).

Chromatin samples were subjected to pre-clearing with 80  $\mu$ l of salmon sperm DNA-saturated agarose A beads for 2 h at 4 °C with rotation. The first immunoprecipitation step was obtained with p63 antibodies (4A4). After several washes, the immunocomplexes were extracted from beads with 100  $\mu$ l of 2% TE/SDS. The second immunoprecipitation step was obtained with YB-1 (Ab12148) antibodies after a 30-fold dilution in DB buffer (50 mM Tris-HCl, 5 mM EDTA, 200 mM NaCl, 0.5% Nonidet P-40, 15 mM DTT). Samples were incubated overnight at 4 °C with rotation. Immunocomplexes were extracted from beads as described above. Immunoprecipitated protein-DNA complexes were subjected to reverse cross-linking and proteinase K treatment. DNA was purified by phenol/chloroform extraction and resuspended in 40  $\mu$ l of TE. 2  $\mu$ l were used for PCR performed with the following primers: *PIK3CA* promoter For, ACAACCCCTGGAATGTGAG, and *PI3KCA* promoter Rev, TGGAAAAGCGTAGGAGCAGT.

**Immunoblot Analyses and Co-immunoprecipitation**—Immunoblots and co-immunoprecipitations were performed as described previously (19). To detect p63/YB-1 interaction in SCC011 cells, 5.0  $\times$  10<sup>5</sup> cells were plated in 60-mm dishes. For co-immunoprecipitations, whole cell extracts, precleared with 30  $\mu$ l of protein A-agarose (50% slurry; Roche Applied Science), were incubated overnight at 4 °C with anti-YB-1 (3  $\mu$ g) or  $\alpha$ -rabbit IgG (3  $\mu$ g). The reciprocal experiment was performed with anti-p63 (2  $\mu$ g) or  $\alpha$ -mouse IgG.

**Far Western Assays**—Far Western assays were conducted according to the protocol described by Cui *et al.* (23). Increasing amounts (0.2, 0.5, and 1.5  $\mu$ g) of  $\Delta$ Np63 $\alpha$  or  $\Delta$ Np63 $\gamma$  recombinant proteins were subjected to SDS-PAGE and transferred to PVDF membrane (IPVH00010 Immobilon Millipore, Milan, Italy). Bovine serum albumin (0.5 and 1.5  $\mu$ g; BSA) was used as control of unspecific binding and equal loading of BSA, and recombinant YB-1 or p63 proteins in far Western blotting was verified by Coomassie staining (data not shown).

**Luciferase Reporter Assay**—MDA-MB-231 cells were co-transfected with  $\Delta$ Np63 $\alpha$ , *PIK3CA* luc promoter, and pRL-TK. *YB-1* gene silencing was carried out 24 h before plasmid

<sup>2</sup> The abbreviations used are: SCC, squamous cell carcinoma; For, forward; Rev, reverse; PARP, poly(ADP-ribose) polymerase; Dox, doxycycline; TRITC, tetramethylrhodamine isothiocyanate; S, speed; P, persistence time; Ab, antibody; HPRT, hypoxanthine-guanine phosphoribosyltransferase.

## $\Delta$ Np63 $\alpha$ Interacts with and Modulates YB-1 Functions

**FIGURE 1.  $\Delta$ Np63 $\alpha$  and YB-1 are co-expressed in squamous carcinoma cell lines.** *a*, whole cell lysates were obtained from H1299 (non-small cell lung carcinoma), A431 (epidermoid carcinoma cell line), and SCC011 and SCC022 (keratinocyte-derived SCC) cells. 30  $\mu$ g of total protein extracts were separated by SDS-PAGE and subjected to immunoblot (*IB*). Proteins were detected with specific antibodies as indicated. Images were acquired with CHEMIDOC (Bio-Rad) and analyzed with the Quantity-ONE software. *b*, A431, SCC011, and SCC022 cells were seeded ( $2.5 \times 10^5$ ) on a 35-mm dish and grown on micro cover glasses (BDH). After 24 h at seeding, cells were fixed and subjected to double immunofluorescence using rabbit primary YB-1 antibody and Fitch-conjugated secondary antibodies (*green*). p63 protein was detected using mouse anti-p63 and Cy3-conjugated secondary antibodies (*red*). Images of merge (*yellow*) show the co-expression of two proteins.

transfection. At 24 h after transfection, cells were harvested in  $1 \times$  PLB buffer (Promega), and luciferase activity was measured using the Dual-Luciferase Reporter system (Promega) using pRL-TK activity as internal control. Firefly-derived luciferase activity was normalized for transfection efficiency. Successful transfection of p63 and silencing of YB-1 was confirmed by immunoblotting.

**RNA Immunoprecipitation**— $1 \times 10^6$  MDA-MB-231 cells were seeded in 100-mm plates and transfected with pcDNA3.1 or  $\Delta$ Np63 $\alpha$  expression plasmids. 24 h after transfection, cells were fixed with 1% formaldehyde for 10 min and washed twice in ice-cold PBS. Cell extracts were prepared in RNA immunoprecipitation buffer (0.1% SDS, 1% Triton, 1 mM EDTA, 10 mM Tris, pH 7.5, 0.5 mM EGTA, 150 mM NaCl) supplemented with complete protease inhibitor mixture (Sigma), and sonication was carried out with BANDELIN SONOPULSE HD2200 instrument under the following conditions: 8 pulses of 4 s at 0.250% of intensity. Cell extracts were incubated with anti-YB-1 (3  $\mu$ g) at 4  $^{\circ}$ C overnight. The RNA-protein immunocomplexes were precipitated with protein A beads (Roche Applied Science) saturated with tRNA and, after reverse cross-link, subjected to real time PCR.

**Semi-quantitative and Real Time PCR**—For PCR analysis, total RNA was isolated using the RNA mini extraction kit (Qiagen, GmbH, Hilden, Germany) according to the manufacturer's instructions. Total RNA (1  $\mu$ g) was used to generate reverse-transcribed cDNA using SuperScript III (Invitrogen). PCR analysis was performed with the following primers: *Twist* (For), 5'-AGAAGTCTGCGGGCTGTG, and *Twist* (Rev), 5'-TCTGCAGCTCCTCGTAAGACT; *YB* (For), 5'-CGCAGTG-TAGGAGATGGAGAG, and *YB* (Rev), 5'-GAACACCACCA-GGACCTGTAA; and *HPRT* (For), 5'-CCT GCT GGA TTA CAT TAA AGC, and *HPRT* (Rev), 5'-CTT CGT GGG GTC CTT TTC.

**FIGURE 2.  $\Delta$ Np63 $\alpha$  interacts with YB-1.** *a*, extracts from SCC011 cells were immunoprecipitated (*IP*) with anti-YB-1 antibodies, and the immunocomplexes were blotted and probed with anti-p63 as indicated. *b*, extracts from SCC011 cells were immunoprecipitated with anti-p63 antibodies, and the immunocomplexes were blotted and probed with anti-YB-1. Samples with no antibody (*no Ab*) or irrelevant  $\alpha$ -mouse and  $\alpha$ -rabbit antibodies were included as controls. *IB*, immunoblot.

**SNAIL1** amplification was performed using Quantitect Primers/Hs *SNAIL1* from Qiagen (GmbH, Hilden, Germany). The amplification sequence consisted of 30 cycles of 94  $^{\circ}$ C for 1 min, 55  $^{\circ}$ C for 1 min, and 72  $^{\circ}$ C for 1 min. PCR products were resolved by 2% agarose electrophoresis. RT-PCR amplification results were analyzed by Quantity One software (Bio-Rad). Real time PCR was performed with a 7500 RT-PCR Thermo Cycler (Applied Biosystem) as already described (22). *HPRT* was used for normalization. The results were expressed with the value relative to *HPRT* (set at 1) for each mRNA sample.

**Immunofluorescence**—A431, SCC011, and SCC022 cells ( $2.5 \times 10^5$ ) were plated in 35-mm dishes and grown on micro cover glasses (BDH). 24 h after seeding, cells were washed with cold phosphate-buffered saline (PBS) and fixed with 4% para-

formaldehyde (Sigma) for 15 min at 4 °C. Cells were permeabilized with ice-cold 0.1% Triton X-100 for 10 min and then washed with PBS. p63 was detected using a 1:200 dilution of the monoclonal antibody 4A4.

YB-1 was detected using 1:100 dilution of the YB-1 antibody (Ab12148). After extensive washing in PBS, the samples were incubated with Cy3-conjugated anti-mouse IgGs and Cy5-conjugated anti-rabbit IgGs at room temperature for 30 min. After PBS washing, the cells were incubated with 10 mg/ml 4',6'-diamidino-2-phenylindole (DAPI) (Sigma) for 3 min. The glasses were mounted with Moviol (Sigma) and examined under a fluorescence microscope (Nikon). Images were digitally acquired and processed using Adobe Photoshop software CS.

H1299 and MDA-MB-231 cells ( $5.0 \times 10^5$ ) were plated in 35-mm dishes, grown on micro cover glasses (BDH), and transfected with 0.2  $\mu$ g of pcDNA<sup>YB-1</sup>/GFP plasmid with or without 0.6  $\mu$ g of  $\Delta$ Np63 $\alpha$  or  $\Delta$ Np63 $\gamma$  plasmid. The GFP empty vector was used as control (data not shown). 24 h after transfection, cells were subjected to the immunofluorescence protocol as described above.

**Cytoskeleton Analysis**—Actin bundles were stained with TRITC-conjugated phalloidin. Cell fixation was performed with 4% paraformaldehyde for 20 min and then permeabilized with 0.1% Triton X-100 (Sigma) in PBS one time for 10 min. Actin staining was done by incubating sample with TRITC-phalloidin (Sigma) in PBS for 30 min at room temperature. Images of fluorescent cells were collected with a fluorescent inverted microscope (IX81, Olympus, Tokyo, Japan) equipped with an ORCA 2.8 digital camera (Hamamatsu Photonics, Japan).

**Time-lapse Microscopy**—SCC011 cells were cultured on 35-mm dishes (Corning, NY) at  $2 \times 10^4$  cells/dish density.  $\Delta$ Np63 $\alpha$  transient silencing was performed as described under "Experimental Procedures." At 48 h from the addition of  $\Delta$ Np63 $\alpha$  si-RNA, the culture dishes were placed in a mini-incubator connected to an automated stage of an optical microscope (Olympus Co., Japan). Images of selected positions of the cell culture were collected in bright field every 10 min for 12 h. The bright field images were mounted to obtain 72-frame time lapse video for each position. Cell trajectories were reconstructed from time lapse video using Metamorph software (Molecular Device, CA). Root mean square speed (*S*) and persistence time (*P*) were chosen as relevant parameters to describe the macroscopic features of cell migration in the different experimental conditions. These parameters were calculated according to the procedure reported by Dunn (24). Briefly, mean-squared displacement of each cell was calculated according to overlapping time interval methods (25). Subsequently, *S* and *P* were estimated by fitting the experimental data of the mean-squared displacement to a linear approximation of the persistent random walk model. The upper limit for the data fitting was set at approximately 200 min for each cell because of the deviation from linearity that was observed at higher time points. The fitting procedure provided (*S*, *P*) pairs for each cell and the statistical significance between *S* and *P* values of the different experimental setups was assessed by performing a nonparametric Kruskal-Wallis test in Matlab (MathWorks, MA). *p* values < 0.05 were considered significant.

**FIGURE 3.  $\Delta$ Np63 $\alpha$  but not  $\Delta$ Np63 $\gamma$  interacts with YB-1.** *a*, H1299 cells were transiently transfected with 5  $\mu$ g of  $\Delta$ Np63 $\alpha$  (left panel) or  $\Delta$ Np63 $\gamma$  (right panel) expression vectors. Equal amounts (1 mg) of extracts were immunoprecipitated (IP) with anti-p63 antibodies (4A4) or unrelated  $\alpha$ -mouse IgG. The immunocomplexes were blotted and probed with anti-p63 and anti-YB-1 antibodies, as indicated. *b*, far Western analysis. Increasing amounts of purified recombinant  $\Delta$ Np63 $\alpha$  (0.2, 0.5, and 1.5),  $\Delta$ Np63 $\gamma$  (0.2, 0.5, and 1.5), or BSA (0.5 and 1.5) were subjected to SDS-PAGE. After Coomassie staining to monitor equal loading, the proteins were transferred to a PVDF membrane, and the filter was incubated with purified YB-1 recombinant protein (0.8  $\mu$ g/ml). After extensive washing, the membrane was subjected to immunoblotting (IB) with YB-1 antibodies followed by ECL detection. Recombinant YB-1 protein (0.1  $\mu$ g) was used as positive control. *m.w.*, molecular weight markers.

Cell migration in H1299 cells was evaluated with a similar approach. Briefly, cells were cultured on 35-mm dishes (Corning, NY) at a density of  $2 \times 10^4$  cells/dish.  $\Delta$ Np63 $\alpha$  expression was induced with 2  $\mu$ g/ml doxycycline for 48 h. 16 h after transfection, cell dishes were placed in a mini-incubator connected to an automated stage of an optical microscope (Cell[caret]R, Olympus Co., Japan). Time 0 images of selected position were collected in fluorescence to localize transfected cells. Then, at the same positions, images were recorded in bright field every 10 min for 12 h. Data analysis was performed as described above.

## RESULTS

**YB-1 Interacts with  $\Delta$ Np63 $\alpha$  in Vitro and in Vivo**—As a result of a comprehensive screening for  $\Delta$ Np63 $\alpha$  interactors, using affinity purification followed by mass spectrometry, we identified a set of proteins with DNA/RNA binding activity, including YB-1 (26). We decided to confirm the interaction between  $\Delta$ Np63 $\alpha$  and YB-1 in SCC as in this cellular context the *TP63* gene is often amplified and/or overexpressed (27). Immunoblots and immunofluorescence assays performed in A431, SCC022, and SCC011 cell lines showed intense signals for both proteins thus confirming that endogenous YB-1 and  $\Delta$ Np63 $\alpha$  are abundantly co-expressed in human squamous carcinoma cells (Fig. 1, *a* and *b*).

We next performed co-immunoprecipitation experiments in SCC011 cells. Immunocomplexes containing  $\Delta$ Np63 $\alpha$  and

## $\Delta$ Np63 $\alpha$ Interacts with and Modulates YB-1 Functions

**FIGURE 4.  $\Delta$ Np63 $\alpha$  induces YB-1 nuclear accumulation.** *a*, H1299 cells ( $2.3 \times 10^5$ ) were seeded at 60% confluency in  $24 \times 24$ -mm sterile coverglasses placed in 60-mm dishes and transiently transfected with GFP-YB-1 expression vector (0.3  $\mu$ g). GFP-YB-1 was detected by direct immunofluorescence. *b*, H1299 cells ( $2.3 \times 10^5$ ) were seeded as described in *a* and transiently transfected with GFP-YB-1 (0.3  $\mu$ g) along with 1  $\mu$ g of  $\Delta$ Np63 $\alpha$  or  $\Delta$ Np63 $\gamma$  expression vectors. Plot shows the percentage of nuclear (dark gray), nucleo-cytoplasmic (gray), and cytoplasmic (white) GFP-YB-1 in cells transfected with  $\Delta$ Np63 $\alpha$  or  $\Delta$ Np63 $\gamma$  expression vectors. Each experimental point is the average of counts performed on 100 cells in five independent fields. Each histogram bar represents the mean and standard deviation of values from three biological replicates. *c*, H1299 cells ( $2.3 \times 10^5$ ) were transfected as described in *b*. GFP-YB-1 was detected by direct immunofluorescence (green), and p63 was detected using anti-p63 antibodies and secondary anti-mouse Cy3-conjugated (red). DAPI was used to stain nuclei.

YB-1 were isolated from total cell lysates, using either antibodies against YB-1 or antibodies against p63 thus confirming the interaction inferred by mass spectrometry (Fig. 2, *a* and *b*). To determine whether YB-1 interacts specifically with the  $\alpha$ -isoform of  $\Delta$ Np63, we transfected p63 null H1299 cells with  $\Delta$ Np63 $\alpha$  or  $\Delta$ Np63 $\gamma$  to perform co-immunoprecipitation assays. As shown in Fig. 3*a*, YB-1 associates with  $\Delta$ Np63 $\alpha$  but not  $\Delta$ Np63 $\gamma$ . This result was also confirmed by far Western blot analysis using  $\Delta$ Np63 $\alpha$ ,  $\Delta$ Np63 $\gamma$ , and YB-1 recombinant proteins purified by affinity chromatography (Fig. 3*b*). The obtained results indicate that the  $\alpha$ -isoform C-terminal region is involved in the association with YB-1, and the interaction between the two proteins requires no additional factors.

**$\Delta$ Np63 $\alpha$  Induces YB-1 Nuclear Accumulation**—It has been reported that YB-1 is ubiquitously expressed and predominantly localized to the cytoplasm (2),  $\Delta$ Np63 $\alpha$  is mainly expressed by basal and myoepithelial cells in skin and glands and is almost completely restricted to the nuclear compartment (29). Because we noticed some overlapping between the p63 and YB-1 immunofluorescence signals in the nucleus of squamous carcinoma cell lines, we sought to determine whether  $\Delta$ Np63 $\alpha$  has an effect on YB-1 subcellular localization. Fusion of YB-1 with the green fluorescent protein (YB-1-GFP) was transfected in H1299 cells. H1299 cells are p63 null and express moderate levels of endogenous YB-1. GFP-positive cells were counted, and 95% showed a strong cytoplasmic signal, although in the remaining 5%, the signal was nuclear or distributed between the nucleus and cytoplasm (Fig. 4, *a* and *b*). A very similar result was observed following  $\Delta$ Np63 $\gamma$  co-transfection (Fig. 4, *b* and *c*, lower panel). Remarkably, combined expression

of YB-1-GFP and  $\Delta$ Np63 $\alpha$  caused a dramatic change of YB-1-GFP subcellular localization. In fact, among the GFP-positive cells, more than 40% showed an intense nuclear signal (Fig. 4, *b* and *c*, upper panel); an additional 20% exhibited YB-1-GFP almost equally distributed between the nucleus and cytoplasm, and the remaining 40% exhibited exclusively cytoplasmic YB-1-GFP (Fig. 4*b*). As expected,  $\Delta$ Np63 $\alpha$  and  $\Delta$ Np63 $\gamma$  immunofluorescence signals were almost exclusively nuclear (Fig. 4*c*).

$\Delta$ Np63 $\alpha$  is a selective nuclear marker of human breast myoepithelial cells.  $\Delta$ Np63 $\alpha$  persists in benign lesions of the breast, although it consistently disappears in invasive carcinomas (30). We transfected  $\Delta$ Np63 $\alpha$  in MDA-MB-231 cells, human metastatic breast carcinoma cells lacking p63 but expressing high level of endogenous YB-1. As shown in Fig. 5, in cells with no detectable p63 signal, YB-1 exhibited a largely prevalent cytoplasmic localization (Fig. 5*a*, white arrows), although 95% of  $\Delta$ Np63 $\alpha$ -expressing cells showed a strong YB-1 nuclear staining (Fig. 5*a*, yellow arrows). We verified this observation by nuclear/cytoplasmic fractionation of MDA-MB-231 cells transfected with  $\Delta$ Np63 $\alpha$  or  $\Delta$ Np63 $\gamma$ . Endogenous YB-1 protein, in MDA-MB-231 cells, was detectable as 50- and 36-kDa immunoreactive forms. Both forms of YB-1 appear to accumulate in the nuclear compartment of cells transfected with  $\Delta$ Np63 $\alpha$  but not  $\Delta$ Np63 $\gamma$  (Fig. 5*b*). Immunoblots with antibodies against PARP-1 (nuclear) and AKT (cytoplasmic) were performed to check for the quality of the fractionation. Interestingly, although the amount of total AKT was comparable, phosphorylated AKT, at serine 473, was enhanced in  $\Delta$ Np63 $\alpha$  but not  $\Delta$ Np63 $\gamma$ -transfected cells (Fig. 5*b*). This observation was in line with previous data showing the specific

**FIGURE 5. Endogenous YB-1 accumulates in the nucleus of breast cancer cells expressing  $\Delta$ Np63 $\alpha$ .** *a*, MDA-MB-231 cells were seeded at 60% confluency ( $2.3 \times 10^5$ ) on  $24 \times 24$ -mm sterile coverglasses placed in 60-mm dishes and transiently transfected with  $1 \mu\text{g}$  of  $\Delta$ Np63 $\alpha$  expression vector. Cells were fixed and subjected to double indirect immunofluorescence using rabbit primary YB-1 antibody and Fitch-conjugated secondary antibodies (green). p63 protein was detected using mouse anti-p63 and Cy3-conjugated secondary antibodies (red). DAPI was used to stain nuclei (blue). A representative image is given of a cell expressing  $\Delta$ Np63 $\alpha$  and showing nuclear endogenous YB-1 (yellow arrows). A representative image is given showing YB-1 cytoplasmic localization in cells bearing no detectable  $\Delta$ Np63 $\alpha$  expression (white arrows). *b*, MB-MDA-231 cells were transiently transfected with a fixed amount ( $5 \mu\text{g}$ ) of an empty vector (mock) and  $\Delta$ Np63 $\alpha$  or  $\Delta$ Np63 $\gamma$  expression vector in 100-mm dishes. 24 h after transfection, cell lysates were fractionated to obtain cytoplasmic (cy) and nuclear (nu) fractions.  $20 \mu\text{g}$  of nuclear and cytoplasmic extracts were separated by SDS-PAGE and subjected to immunoblot. Proteins were detected with specific antibodies, as indicated. PARP and total AKT were used as nuclear and cytoplasmic controls, respectively, to check for cross-contamination. Images were acquired with CHEMIDOC (Bio-Rad) and analyzed with the Quantity-ONE software.

ability of the  $\Delta$ Np63 $\alpha$  isoform to promote PI3K/AKT pathway activation (31).

We then evaluated the contribution of  $\Delta$ Np63 $\alpha$  to YB-1 subcellular distribution in SCC011 cells expressing both proteins endogenously. To this aim we analyzed YB-1 subcellular distribution by immunoblot on nuclear/cytoplasmic fractions after depletion of  $\Delta$ Np63 $\alpha$  by siRNA. As shown in Fig. 6, *a* and *b*, following p63 knockdown the YB-1 nuclear pool was dramatically reduced, and the 36-kDa form of YB-1 became detectable (Fig. 6*a*).

**$\Delta$ Np63 $\alpha$  and YB-1 Bind to the PIK3CA Gene Promoter and Cooperate in Its Transcriptional Activation**—The PIK3CA gene encodes the p110 $\alpha$  catalytic subunit of the PI3K and is a well characterized YB-1 direct transcriptional target (32). We speculated that  $\Delta$ Np63 $\alpha$  should increase PIK3CA promoter activity because of its ability to cause YB-1 nuclear accumulation. We tested this hypothesis by luciferase assays. As shown in Fig. 7*a*,  $\Delta$ Np63 $\alpha$  transfection in MDA-MB-231 cells caused a relevant increase of the PIK3CA promoter activity that was consistently attenuated by YB-1 knockdown. In addition, we observed that  $\Delta$ Np63 $\alpha$  was able to transactivate the PIK3CA promoter in a dose-dependent manner, although  $\Delta$ Np63 $\gamma$  was completely ineffective (Fig. 7*b*).

The role of  $\Delta$ Np63 $\alpha$  and YB-1 in PIK3CA promoter activation was thoroughly investigated by chromatin immunoprecipitation (ChIP). We first performed ChIP assays in MDA-MB-231 cells transfected with  $\Delta$ Np63 $\alpha$  or  $\Delta$ Np63 $\gamma$  using anti-p63 (4A4) antibodies and PIK3CA promoter-specific primers. As shown in Fig. 8*a*,  $\Delta$ Np63 $\alpha$ , but not  $\Delta$ Np63 $\gamma$ , binds to the genomic sequence of the PIK3CA promoter.

Then we evaluated the effect of  $\Delta$ Np63 $\alpha$  expression on the binding of YB-1 to the PIK3CA promoter. FLAG-YB-1 was transfected, in MB-MDA-231 cells, with or without  $\Delta$ Np63 $\alpha$  plasmid. ChIP was carried out with anti-FLAG antibodies and coupled with quantitative real time PCR. As show in Fig. 8*b*, FLAG-YB-1 efficiently binds to the PIK3CA promoter, and its binding was substantially increased by  $\Delta$ Np63 $\alpha$ . Finally, by using a sequential chromatin immunoprecipitation assay (Re-ChIP) in SCC011 cells, expressing endogenous  $\Delta$ Np63 $\alpha$  and YB-1, we found that both proteins are recruited to the PIK3CA

**FIGURE 6.  $\Delta$ Np63 $\alpha$  depletion reduces the pool of nuclear YB-1.** *a*, SCC011 cells were seeded at 60% confluency ( $1.5 \times 10^6$ ) in 100-mm dishes. 24 h after seeding, cells were transiently silenced with IBONI p63-siRNA pool (20 nm final concentration). 48 h after p63-silencing, cell lysates were fractionated to obtain cytoplasmic (cy) and nuclear (nu) fractions. Nuclear and cytoplasmic extracts were separated by SDS-PAGE and subjected to immunoblot. Proteins were detected with specific antibodies, as indicated. PARP and total AKT were used as nuclear and cytoplasmic control respectively, to check for cross-contamination. Images were acquired with CHEMIDOC (Bio-Rad) and analyzed with the Quantity-ONE software. *b*, plots show the percentage of YB-1 subcellular distribution in control sample (upper panel) and in p63-silenced sample (lower panel) considering the total amount of YB-1 between the nucleus and cytoplasm as 100%.

proximal promoter suggesting that they cooperate in PIK3CA gene transactivation as a complex (Fig. 8*c*).

**$\Delta$ Np63 $\alpha$  Affects YB-1 Binding to SNAIL and YB-1 mRNAs**—Cytoplasmic localization of YB-1 was associated with binding and translational activation of SNAIL1 mRNA (33). Snail1 protein is a transcriptional repressor of  $\Delta$ Np63 $\alpha$  and E-cadherin and promotes the epithelial-mesenchymal transition in several epithelium-derived cancer cell lines (34). We first observed that  $\Delta$ Np63 $\alpha$  overexpression in MB-MDA-231 caused a reduction of SNAIL1 protein level (Fig. 9*a*). Such a reduction was not associated with a decrease of SNAIL1 mRNA levels (Fig. 9*b*) thereby suggesting that the SNAIL1 protein was down-regulated at the translational level. We hypothesized that the spe-

## $\Delta$ Np63 $\alpha$ Interacts with and Modulates YB-1 Functions

**FIGURE 7.  $\Delta$ Np63 $\alpha$  and YB-1 activates the PI3KCA gene promoter.** *a*, MB-MDA-231 cells were transfected with 1  $\mu$ g of PI3KCA promoter luciferase reporter plasmid. The luciferase activity upon siRNA-mediated knockdown of endogenous YB-1 was measured in the presence or absence of  $\Delta$ Np63 $\alpha$  expression. Values are shown as mean  $\pm$  S.D. of three biological replicates. The extent of YB-1 knockdown was documented by Western blotting as shown in the lower panel. *b*, MB-MDA-231 cells were seeded at 60% confluency ( $1.2 \times 10^6$ ) in 100-mm dishes and transiently transfected with 1  $\mu$ g of PI3KCA promoter luciferase reporter plasmid and the indicated amounts of  $\Delta$ Np63 $\alpha$  or  $\Delta$ Np63 $\gamma$  plasmid. Values are the mean  $\pm$  S.D. of three independent experimental points. Lower panel, immunoblotting (IB) with indicated antibodies to detect proteins in samples transfected with different amounts of  $\Delta$ Np63 $\alpha$  or  $\Delta$ Np63 $\gamma$ .

**FIGURE 8.  $\Delta$ Np63 $\alpha$  increases YB-1 binding to the PI3KCA gene promoter.** *a*, MDA-MB-231 cells were seeded at 60% confluency ( $1.2 \times 10^6$ ) in 100-mm dishes and transiently transfected with  $\Delta$ Np63 $\alpha$  or  $\Delta$ Np63 $\gamma$  plasmid (5  $\mu$ g). After formaldehyde cross-linking, the DNA-protein complexes were immunoprecipitated (IP) with anti-p63 (4A4) antibody. Immunoprecipitated DNA was PCR-amplified with PI3KCA promoter oligonucleotides and 18 S rRNA oligonucleotides (right). The data obtained from the ChIP assay were measured by densitometry and are presented as signal relative to the input (left). *b*, MDA-MB-231 cells were seeded at 60% confluency ( $1.2 \times 10^6$ ) in 100-mm dishes and transiently transfected with 3 $\times$ FLAG empty vector or 3 $\times$ FLAG-YB-1 (5  $\mu$ g) plasmid with or without  $\Delta$ Np63 $\alpha$  (2.5  $\mu$ g) expression vector. The cells were cross-linked with formaldehyde, and DNA-protein complexes were immunoprecipitated with anti-FLAG antibody or irrelevant IgG antibody as negative control. The DNA immunoprecipitates were analyzed by quantitative PCR using PI3KCA or GAPDH promoter oligonucleotides. Quantitative RT-PCR results were analyzed with the  $\Delta\Delta C_T$  method and expressed as fold of enrichment with respect to the IgGAb control samples. Values are represented as the mean of three independent experiments. *c*, SCC011 cells at 85% confluency were fixed with formaldehyde, and the DNA-protein complexes were subjected to sequential ChIP with anti-p63 (4A4), anti-YB-1 (Ab12148), or irrelevant IgG antibody as described under "Experimental Procedures." Immunoprecipitated DNA was PCR-amplified with PI3KCA promoter primers and 18 S rRNA primers to check the quality of the input chromatin and the cleaning of the other samples.

cific association of  $\Delta$ Np63 $\alpha$  with YB-1 would reduce the amount of YB-1 bound to the *SNAIL1* transcript. To test this hypothesis, we performed RNA-immunoprecipitation coupled with real time PCR to quantitate the amount of *SNAIL1* mRNA bound to endogenous YB-1, in mock and  $\Delta$ Np63 $\alpha$ -transfected MDA-MB-231 cells. The obtained results confirm that  $\Delta$ Np63 $\alpha$  reduces the amount of YB-1 bound to *SNAIL1* tran-

script (Fig. 9c). A similar analysis performed on the *YB-1* transcript gave the same result (Fig. 9d).

**$\Delta$ Np63 $\alpha$  Affects Cell Shape and Motility**—So far, little attention has been focused on the effects of  $\Delta$ Np63 $\alpha$  on epithelial cancer cell morphology and motility. We have unexpectedly noted a profound change in cell morphology when SCC011 cells were depleted of  $\Delta$ Np63 $\alpha$  by siRNA. SCC011 cells are

**FIGURE 9.  $\Delta$ Np63 $\alpha$  affects SNAIL1 protein level and YB-1 binding to SNAIL1 and YB-1 mRNAs in MDA-MB-231 cells.** *a*, MDA-MB-231 cells were transfected with an empty vector (*mock*) or a fixed amount (1  $\mu$ g in 60-mm dishes) of  $\Delta$ Np63 $\alpha$  or  $\Delta$ Np63 $\gamma$  expression vector. 24 h after transfection, cells were harvested, and total extracts were prepared. 20  $\mu$ g of each extract were loaded on SDS-PAGE and subjected to immunoblot with the indicated antibodies. *b*, MB-MDA-231 cells were transfected with an empty vector or  $\Delta$ Np63 $\alpha$  encoding plasmid. 24 h after transfection, total RNA was purified and retrotranscribed as described under "Experimental Procedures." The expression level of  $\Delta$ Np63 $\alpha$  was checked by immunoblot (*right panel*). WB, Western blot. PCR was performed with primers designed to specifically amplify SNAIL1, TWIST, or HPRT transcripts and analyzed by agarose gel electrophoresis (*left panel*). Plot showing the level of SNAIL1 and TWIST transcripts was normalized respect to HPRT. Values are the mean of three independent experiments (*lower panel*). Nuclear extracts from  $\Delta$ Np63 $\alpha$  transfected MB-MDA-231 cells were immunoprecipitated with anti-YB-1 antibody. After reverse cross-linking, the YB-1-bound RNA was purified, retrotranscribed, and subjected to quantitative RT-PCR analysis using oligonucleotides designed to specifically amplify SNAIL1 transcript (*c*) or YB-1 transcript (*d*). Plots represent the % of enrichment of SNAIL1/YB-1 transcript normalized as indicated under "Experimental Procedures." 1:50 of the input extract was loaded as control. The values are the means  $\pm$  S.D. of three biological replicates.

round in shape, and under high density culture conditions, they appear orderly arranged with tight cell-cell contacts. Conversely,  $\Delta$ Np63 $\alpha$ -depleted cells tend to lose their contacts and exhibited an unusual extended phenotype that was distinct from that of the control cells cultured at the same density (Fig. 10*a*). The unusual change in morphology of  $\Delta$ Np63 $\alpha$ -depleted cells indicated possible alterations in actin cytoskeleton organization. Therefore, we examined the status of actin stress fibers at the level of individual cells, in control and  $\Delta$ Np63 $\alpha$ -depleted cells, with TRITC-phalloidin followed by fluorescent microscopy. As shown in Fig. 10*b*, the control cells exhibited a diffuse pattern of actin staining, although  $\Delta$ Np63 $\alpha$ -depleted cells displayed a more substantial enhancement of actin stress fibers suggesting an inhibitory effect of  $\Delta$ Np63 $\alpha$  on cancer cell motility. Remarkably, compared with the control cells,  $\Delta$ Np63 $\alpha$ -depleted SCC011 cells express higher levels of N-cadherin and lower amounts of E-cadherin, suggesting that they were undergoing epithelial to mesenchymal trans-differentiation (Fig. 10*c*).

We determined the influence of  $\Delta$ Np63 $\alpha$  on cell motility by time-lapse microscopy using siRNA-based silencing of endogenous  $\Delta$ Np63 $\alpha$  in SCC011 cells. Silencing efficiency was about 90% as determined by fluorescent staining for p63 protein (data

not shown). SCC011 migration was characterized by oscillations of the cells around their initial adhesion site. These oscillations occurred at random directions in space, as reported in the windrose plots of the trajectories (Fig. 10*d*, *inset*). Conversely,  $\Delta$ Np63 $\alpha$  silenced cells display much wider oscillations (Fig. 10*d*). These observations were confirmed by the analysis of the migration parameters "Speed (*S*)" and "persistence time (*P*)" that are computed from cell tracks and are a measure of the frequency of cell steps and of the minimum time that is necessary for a cell to significantly change direction. According to these parameters, SCC011 exhibit lower speeds ( $p < 0.05$ ) and shorter persistence times ( $0.26 \pm 0.03 \mu\text{m}/\text{min}$  and  $6.5 \pm 0.7 \text{ min}$ ) with respect to  $\Delta$ Np63 $\alpha$ -depleted cells ( $0.44 \pm 0.05 \mu\text{m}/\text{min}$  and  $8.2 \pm 2.3 \text{ min}$ ). These data indicate a role for  $\Delta$ Np63 $\alpha$  in affecting cell motility. In particular, the absence of  $\Delta$ Np63 $\alpha$  causes the cells to migrate faster with less frequent direction changes, which enables the cells to explore larger areas in a fixed time interval.

To gain a better insight into the effects of the interaction of  $\Delta$ Np63 $\alpha$  and YB-1 on cell migration, we used the genetically modified Tet-On-H1299 cells expressing  $\Delta$ Np63 $\alpha$  upon Dox addition (Fig. 11*a*). Cells were transfected with GFP or GFP-

## $\Delta$ Np63 $\alpha$ Interacts with and Modulates YB-1 Functions

**FIGURE 10.  $\Delta$ Np63 $\alpha$  affects cell shape and motility.** *a*, SCC011 cells were transiently silenced with IBONI p63-siRNA pool (20 nm final concentration). Cells were fixed and subjected to double immunofluorescence 48 h after silencing, as already described. *b*, protein extracts from control and p63-depleted cells were separated by SDS-PAGE and subjected to immunoblot. Proteins were detected with specific antibodies. *c*, actin staining with TRITC-conjugated phalloidin of control and  $\Delta$ Np63 $\alpha$ -depleted SCC011 cells (see "Experimental Procedures"). Cell expressing  $\Delta$ Np63 $\alpha$  displayed a round morphology. Conversely,  $\Delta$ Np63 $\alpha$ -depleted cells had a polarized morphology with more evident lamellipodia and trailing edge. *d*, windrose plot of trajectories described by  $\Delta$ Np63 $\alpha$  depleted SCC011 or SCC011 control cells (*inset*) in 12-h time lapse video. Only 15 cell trajectories were reported in each plot for graphical clarity. *E-cad*, E-cadherin; *N-cad*, N-cadherin.

**FIGURE 11. Effects of  $\Delta$ Np63 $\alpha$  and YB-1 on cell migration.** *a*, after being subjected to the migration experiment, extracts from Tet-On H1299 cells, induced (+*dox*) or not (-*dox*) with doxycycline, were prepared and subjected to immunoblot analysis to monitor  $\Delta$ Np63 $\alpha$  induced expression. *b*, trajectories of GFP/YB-1- or GFP (*insets*)-transfected cells. Inducible H1299/ $\Delta$ Np63 $\alpha$  cells were transfected with a fixed amount of GFP-YB-1 (1  $\mu$ g) or GFP empty vector (1  $\mu$ g). 4 h after transfection, 2  $\mu$ g/ml doxycycline was added to induce  $\Delta$ Np63 $\alpha$  expression, and 16 h later uninduced (-*Dox*) and induced (+*Dox*) cells were tracked with optical microscopy. Plots represent data from the following number of cells (YB-1/-*dox* 79; YB-1/+*dox* 69; control/-*dox* 44; control/+*dox* 49). *c*, bar chart of speed (*S*; gray bars) and persistence ratios (*P*; white bars). The ratios are computed by dividing the population average values of speed and persistence for H1299 control cells (-*Dox*) and  $\Delta$ Np63 $\alpha$ -expressing cells (+*Dox*).

YB-1 plasmid, and unfluorescent and fluorescent cells were tracked separately. Cells migrated describing trajectories that are randomly distributed in plane, as depicted in plots of Fig. 10*b*. In Dox-free medium (–Dox), GFP-YB-1-expressing cells were characterized by a significantly higher *S* and lower *P* ( $0.69 \pm 0.04 \mu\text{m}/\text{min}$  and  $8.4 \pm 0.5 \text{ min}$ ) than cells expressing GFP alone ( $0.54 \pm 0.05 \mu\text{m}/\text{min}$  and  $15 \pm 2.1 \text{ min}$ ). Remarkably, in Dox-supplemented medium (+Dox), GFP-YB-1-expressing cells exhibited *S* and *P* values ( $0.62 \pm 0.05 \mu\text{m}/\text{min}$  and  $9.2 \pm 1.0 \text{ min}$ ), which were not significantly different from those of cells transfected with GFP alone ( $0.68 \pm 0.05 \mu\text{m}/\text{min}$  and  $8.6 \pm 0.9 \text{ min}$ ) (Fig. 10*c*). We also noticed that unfluorescent cells were characterized by the highest *S* values suggesting that expression of the green fluorescent protein alters cell migration to some extent (data not shown). However, *S* of unfluorescent cells with or without Dox was comparable. Overall, these data indicate that  $\Delta$ Np63 $\alpha$  expression can revert the increase of cell motility induced by YB-1-enforced expression.

### DISCUSSION

In normal epithelium,  $\Delta$ Np63 $\alpha$  protein expression is abundant in basal cells and decreases with differentiation (35). Transient overexpression of  $\Delta$ Np63 $\alpha$  was shown to enhance cell proliferation, inhibit differentiation, and promote malignant conversion of primary keratinocytes (36, 37). However, enhanced and stable expression of  $\Delta$ Np63 $\alpha$ , as seen in human squamous cell carcinomas, is believed to alter skin homeostasis and be directly implicated in the etiology of human cutaneous carcinomas. In normal cells, YB-1 is mainly detected in the cytosol, particularly at the perinuclear region, with a minor pool located in the nucleus (38). Nuclear localization of YB-1 appears to be critical for its role in promoting proliferation. In fact, in the nucleus YB-1 may not only act as a transcription factor of various genes that are closely associated with DNA replication, cell proliferation, and multidrug resistance but also exert SOS signaling against genotoxic factors that could undermine the integrity of highly proliferative basal cells.

This report unveils a novel protein-protein association involving  $\Delta$ Np63 $\alpha$  and YB-1. This specific association results in the accumulation of nuclear YB-1, as shown by immunofluorescence assays and nuclear-cytoplasmic fractionation. Moreover, we have demonstrated that  $\Delta$ Np63 $\alpha$  and YB-1 cooperate in *PIK3CA* gene activation with both being recruited to the *PIK3CA* proximal promoter, thereby supporting the hypothesis that this molecular association can function as a pro-survival mechanism. It's worth mentioning, however, that additional mechanisms have been described to activate and translocate YB-1 to the nucleus (8).

Into the cytoplasm, YB-1 is known to act as a positive translational regulator of SNAIL1, a potent epithelial to mesenchymal transition inducer able to reduce cell-cell adhesion and increase migratory properties of cancer cells (33). Accordingly, we have observed that enforced expression of YB-1 in tumor cells increases their motility and migration speed. Remarkably, we have shown that  $\Delta$ Np63 $\alpha$ -enforced expression reduces the activating binding of YB-1 to the *SNAIL1* transcript and restores a normal migratory behavior to YB-1-overexpressing cells. However, depletion of endogenous  $\Delta$ Np63 $\alpha$  in SCC cells

results in SNAIL1 up-regulation, E-cadherin repression, and increased cell motility.

Finally, cytoplasmic YB-1 is known to bind to actin filaments and causes actin fibers to bundle *in vitro* (39). It was also demonstrated that YB-1 plays a relevant role in the organization of the actin cytoskeleton by binding to F-actin and microtubules (40, 41). In normal conditions, SCC011 cells are round in shape and exhibit a more diffuse actin distribution, as determined by phalloidin staining. Here, we show that  $\Delta$ Np63 $\alpha$  depletion in SCC cells promotes morphological changes and causes a profound cytoskeleton reorganization.  $\Delta$ Np63 $\alpha$ -depleted cells had a polarized morphology with more evident lamellipodia and trailing edge. They also exhibited mature stress fibers suggesting a pro-migratory behavior. The alterations in cell morphology and motility of  $\Delta$ Np63 $\alpha$ -depleted SCC cells closely resemble the process of epithelial to mesenchymal transition (28). We can speculate that the absence of  $\Delta$ Np63 $\alpha$  can promote F-actin polymerization by YB-1 thereby promoting the formation of stress fibers.

All together, our data indicate that  $\Delta$ Np63 $\alpha$ -YB-1 association into the nucleus can act as a pro-proliferative/survival mechanism, although the loss of p63 predisposes the acquisition of mesenchymal characteristics at least in part by restoring YB-1 cytoplasmic functions. Moreover, we suggest that the balance between  $\Delta$ Np63 $\alpha$  and YB-1 protein levels could be critical for the transition to a mesenchyme-like phenotype explaining, at least in part, why  $\Delta$ Np63 $\alpha$  depletion promotes cancer cell invasion and spreading (35).
